

I am concerned about world wide heating of the planet and the resulting temperature changes which will cause the following problems:

1. The Gulf Stream in the Atlantic is already slowing down with the potential dramatic cooling of Europe,
2. The glazier melting causing Major Rivers to loose their source of water e.g. The Ganges River which will affect millions of people in India and Bangladesh. Therefore the food shortages will be affected by climate change as well as the lack of water from the current large rivers flowing from the Glaziers of the Himalayas.
3. The North Pole area is already affected by sheet ice melt therefore the habitat is changing much quicker then the flora and fauna can adapt. Many species are thus already under great stress due to the snow and ice melting. Many areas of the world are now subject to weather instability. Agriculture is therefore becoming a high risk occupation. World shortages of food may very real in the near future especially with the added higher prices of energy
